Table of Contents

- Introduction
- Basics:
 - Definitions
 - Classifications
 - Uni / Multi / Any / Broad -cast
- Internet service: connection oriented – connectionless.
- OSI and TCP/IP Model

A network

A network is a set of hardware and software that enables the transmission of information from one sender to one or more receivers.

- Examples:
 - Plain Old Telephone System (POTS)
 - GSM
 - Broadcast networks (TV, Radio,..)
 - Computer Networks (Internet, home networks, proprietary networks)

Classifications

Based on range

Wide Area Network

Metropolitan Area Network

Local Area Network

Personal Area Network

Based on topologies

Future

- Connected Fridge tells the connected TV to show ads about tomato sauce because of the high consumption of that.
- You control your house's lights with your phone.
- Usage and connected machines is expected to grow exponentially.

Transmission Modes

- Unicast (Point-to-Point)

one **sender**
one **receiver**
example : telephone

Transmission Modes

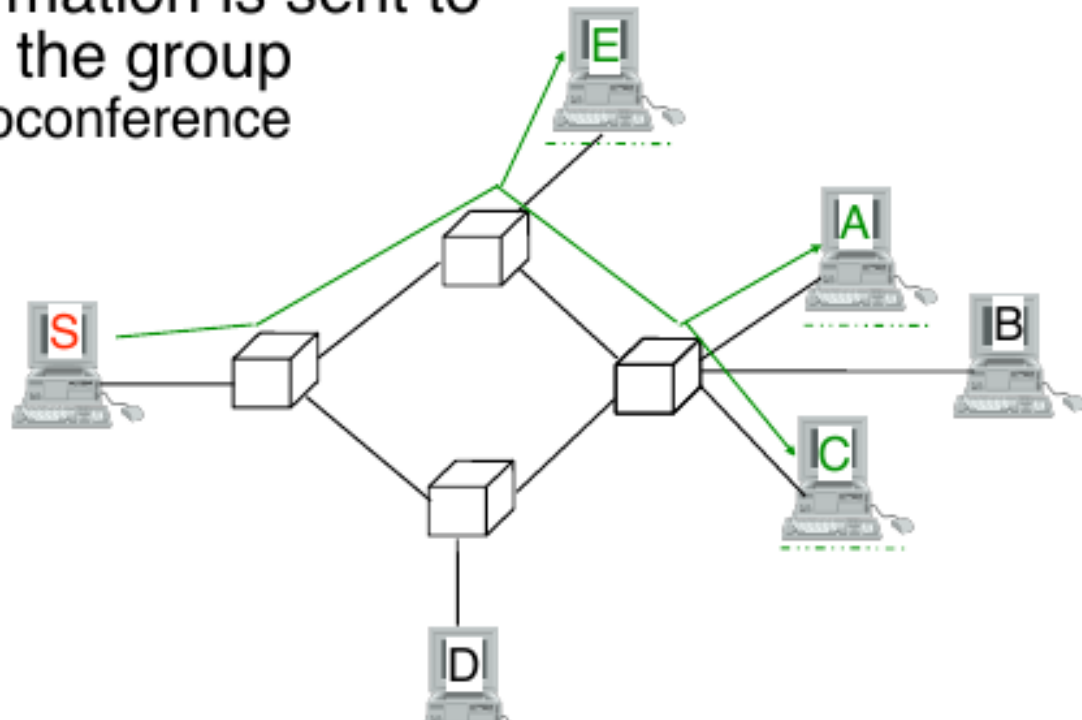

- Multicast (Point-to-multipoints)

one **sender**

a **group of receivers**

The same information is sent to
all members of the group

example : videoconference

Transmission modes

- Broadcast

- The same information is sent to everyone reachable on the network.

- Example: the radio

- Anycast

- The information is sent from one sender to one receiver, among a group of possible receivers.

Sketch of the internet

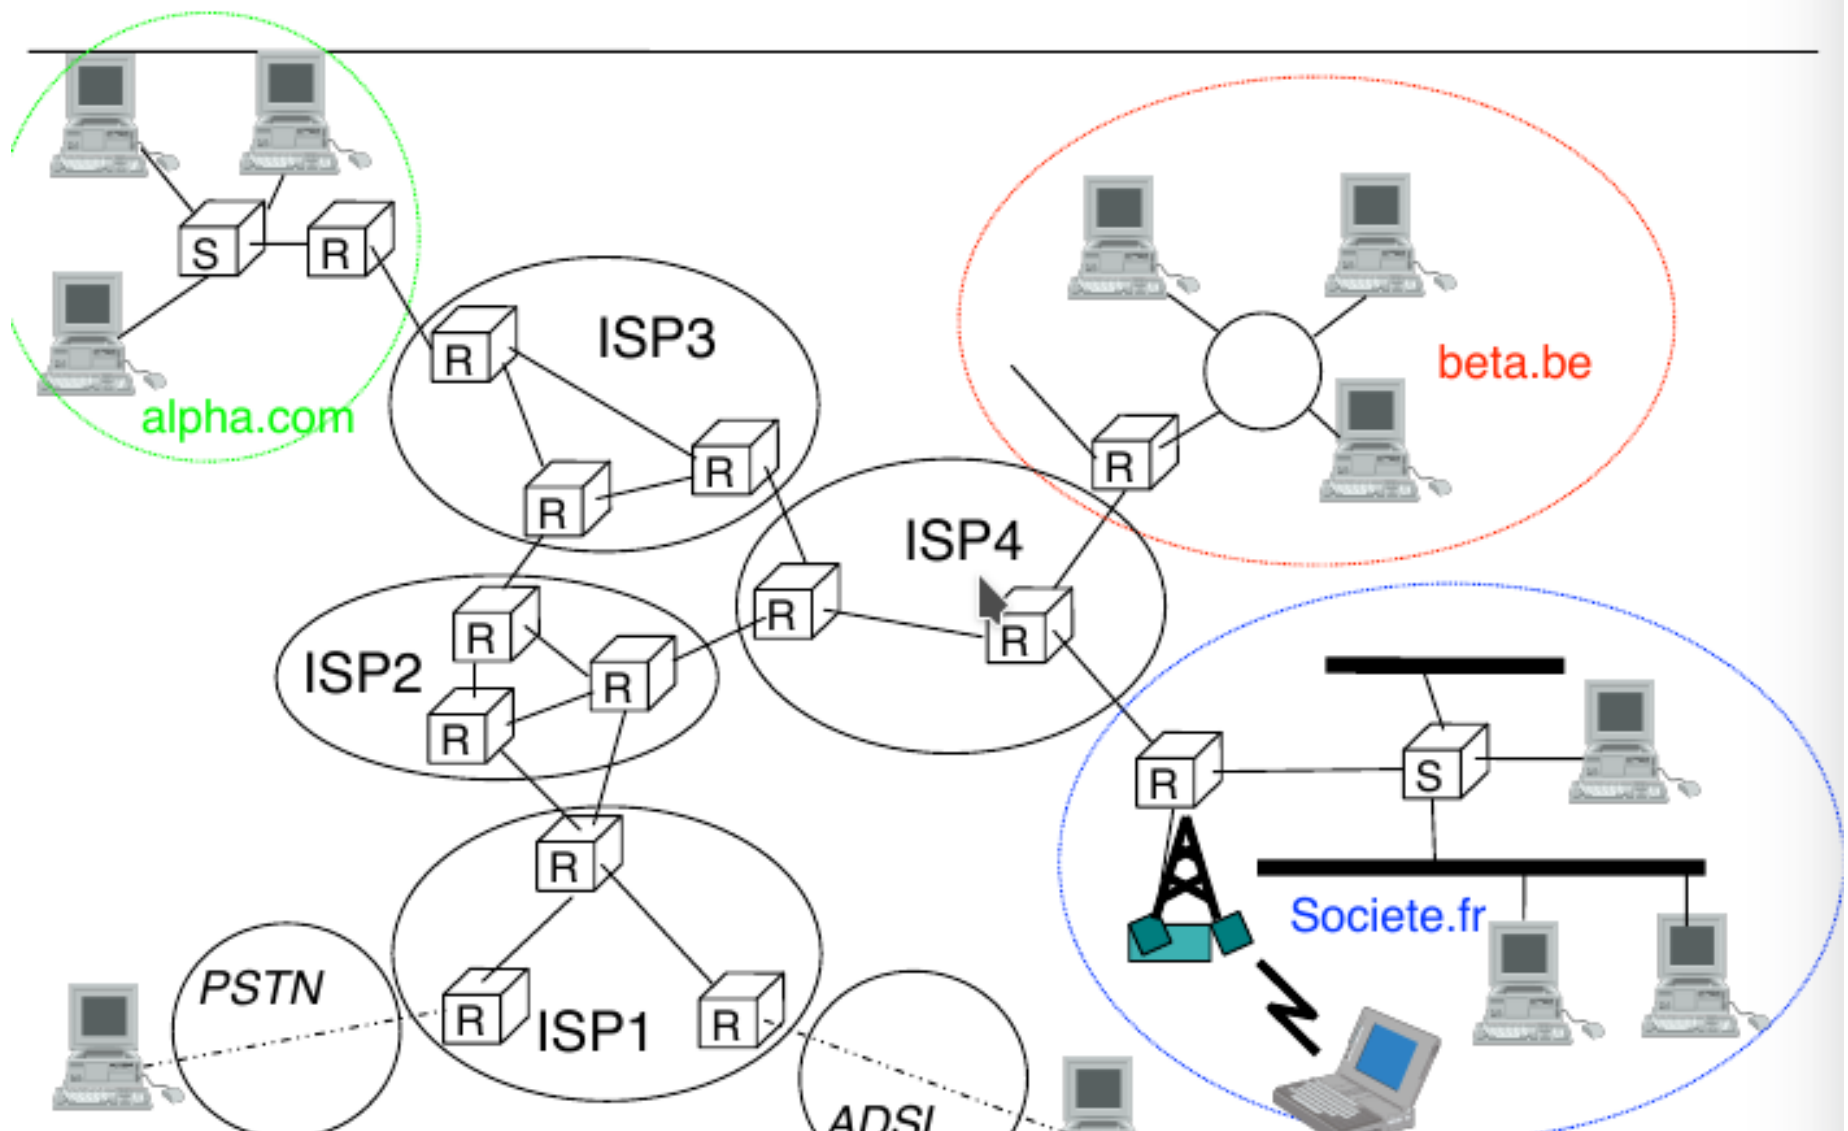

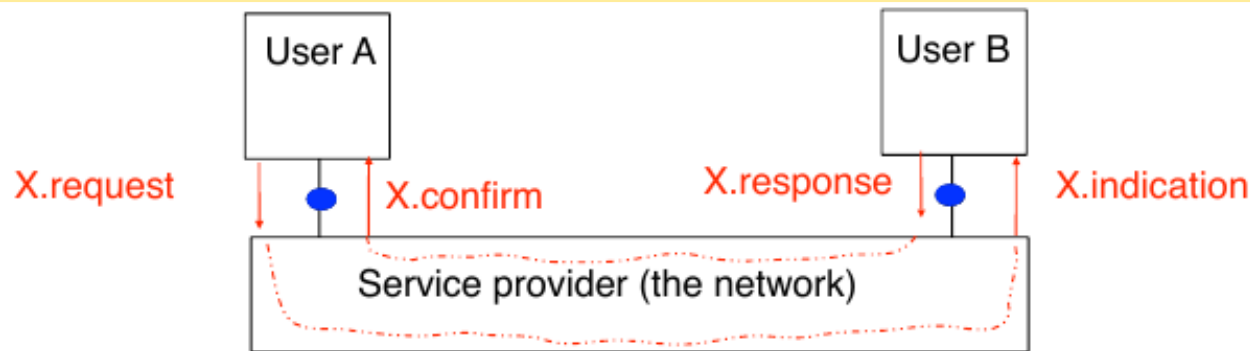

Table of Contents

- ~~Introduction~~
- ~~Basics:~~
 - ~~Definitions~~
 - ~~Classifications~~
 - ~~Uni / Multi / Any / Broad-cast~~
- Internet service: connection oriented – connectionless
- OSI and TCP/IP Model

Service Provider: connection-oriented / connectionless

- Before reaching the targeted receiver, the data goes through a network provider (ISPs).

- X.request
 - request from a user to a service provider
- X.indication
 - primitive generated by the network provider to a user (often related to an earlier and remote X.request primitive)
- X.response
 - primitive used to answer to an earlier X.indication primitive
- X.confirm
 - primitive generated by the network provider to a user (related to a remote X.response primitive)

Service Provider: connectionless

Goal

Allow a sender to quickly send a message to one receiver

Principle

The sender places the message to be transmitted in a DATA.req primitive and gives it to the network provider
The network provider carries the message and delivers it to the receiver by using a DATA.ind primitive

Utilisation

useful to send short-length messages
example : post office

Service Provider: connectionless

Service Provider: Variations

confirmation

primitive DATA.confirm delivered by provider to sender to confirm (acknowledge) that some message has been delivered to destination

reliability

- reliable connectionless service (no errors)
- unreliable connectionless service (errors are possible)

protection against transmission errors

service may or may not detect/correct errors

protection against losses

the service may or cannot lose messages

in sequence delivery

The service may or not guarantee in-sequence delivery for all messages sent by one source

Service Provider: connection-oriented

- Goal

Create a logical binding (connection) between two users to allow them to efficiently exchange messages

- Main phases of service

- Connection establishment
- Data transfer: both users can send and receive messages over connection
- Connection release

- Utilisation

- useful when the two users either
 - must exchange a large number of messages
 - need a structured exchange

- example : telephone

Service Provider: connection-oriented

Connection establishment

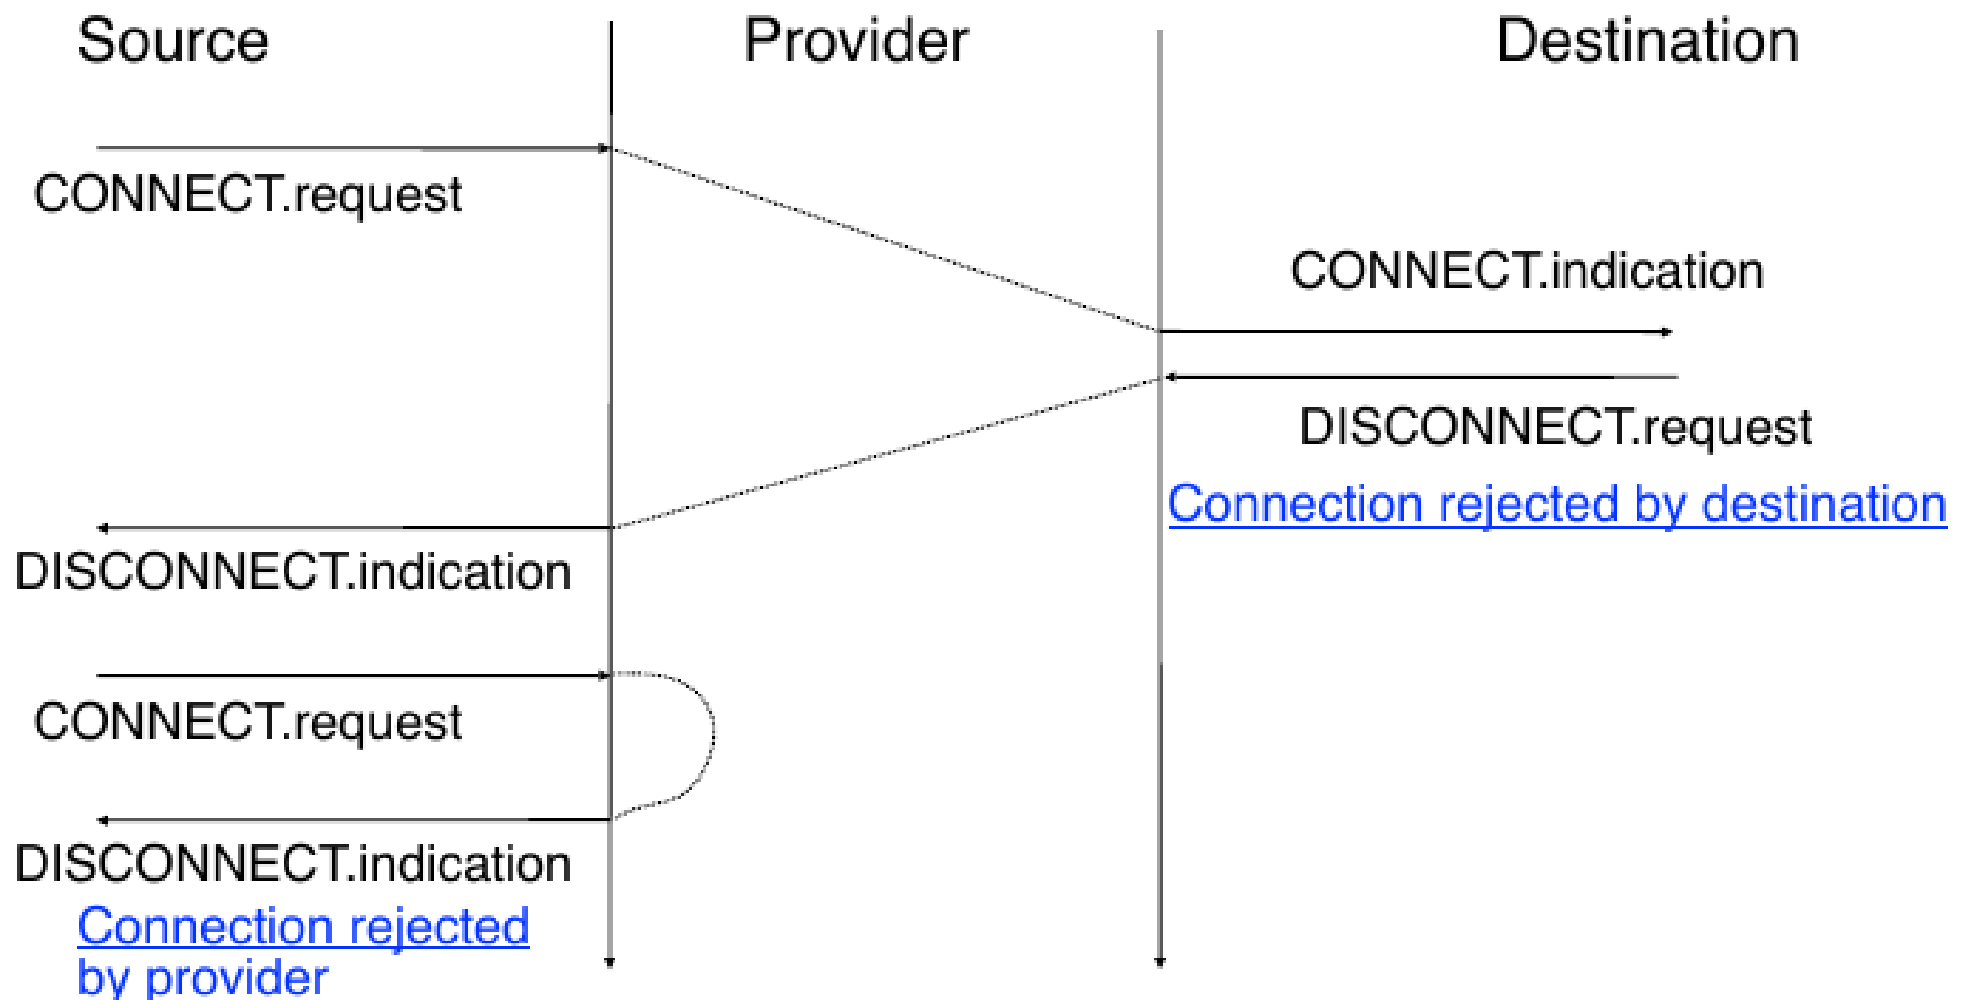

Primitives

CONNECT.request
CONNECT.indication
CONNECT.response
CONNECT.confirm

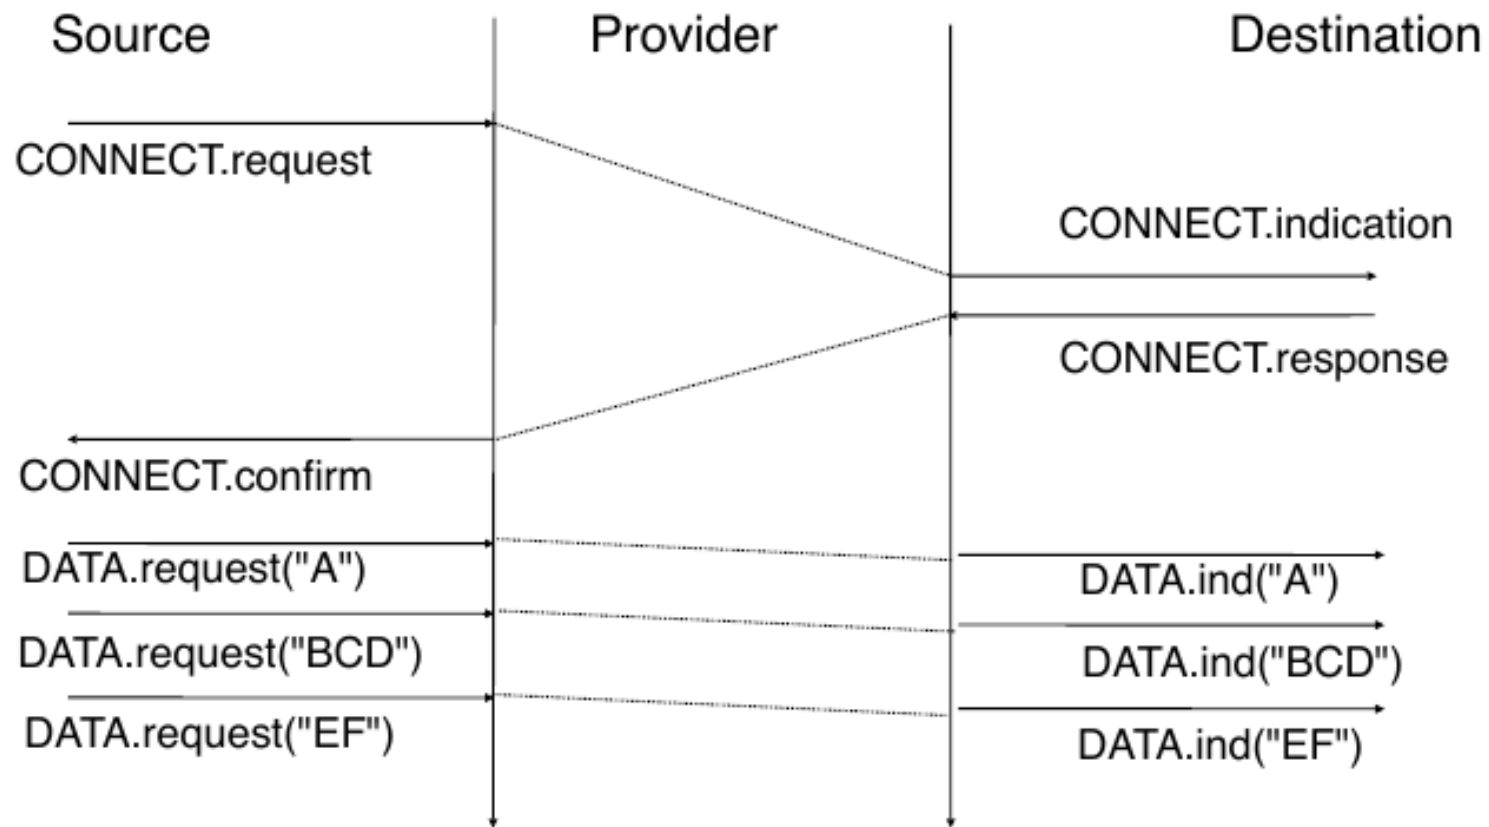

Service Provider: connection-oriented

Connection can be rejected

Service Provider: connection-oriented

Message Mode

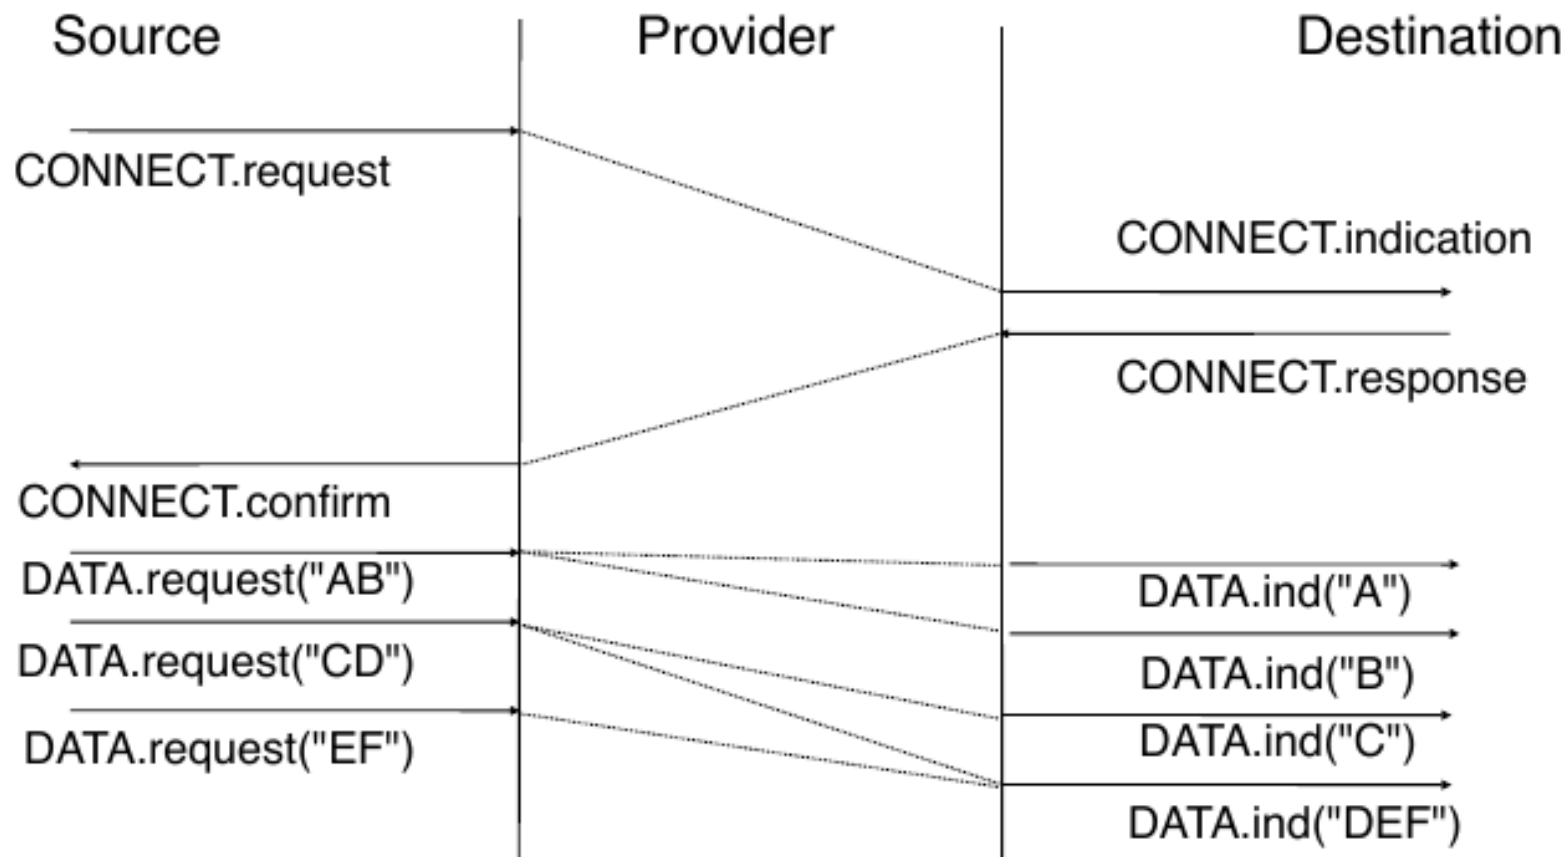

Provider delivers one Data.ind for each Data.req

Service Provider: connection-oriented

Stream Mode

The providers delivers a **stream of characters** from source to destination

Service Provider: connection-oriented

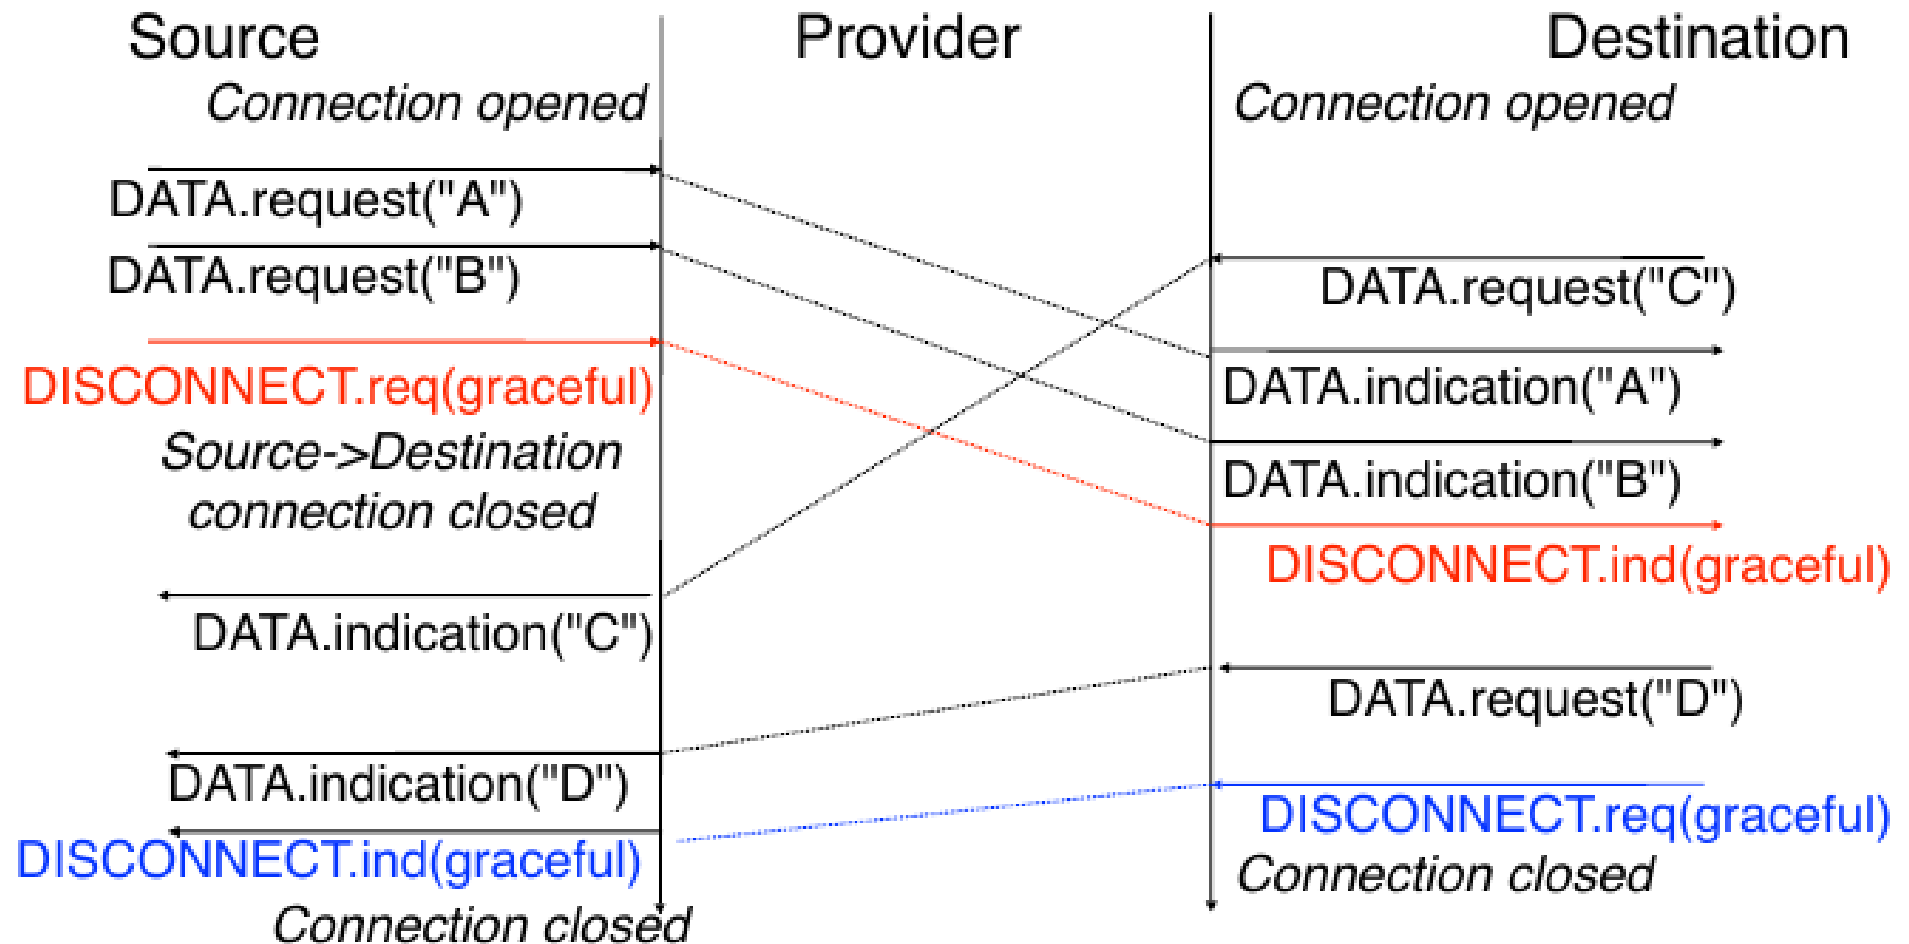

Abrupt Release

Such an abrupt connection release can be caused by the network provider or by the users

Service Provider: connection-oriented

Graceful Release

Service Provider: connection-oriented

Possible Characteristics

- Bidirectional flow
- Reliability
 - Delivery in sequence
 - No losses
 - Data integrity
- Message or stream mode
- Abrupt or Graceful release

Table of Contents

- ~~Introduction~~
- ~~Basics:~~
 - ~~Definitions~~
 - ~~Classifications~~
 - ~~Uni / Multi / Any / Broad-cast~~
- ~~Internet service: connection oriented—
connectionless~~
- OSI and TCP/IP Model

OSI Model

Problem

How is it possible to reason about complex systems such as computer networks or the Internet ?

Solution

Divide the network in layers.

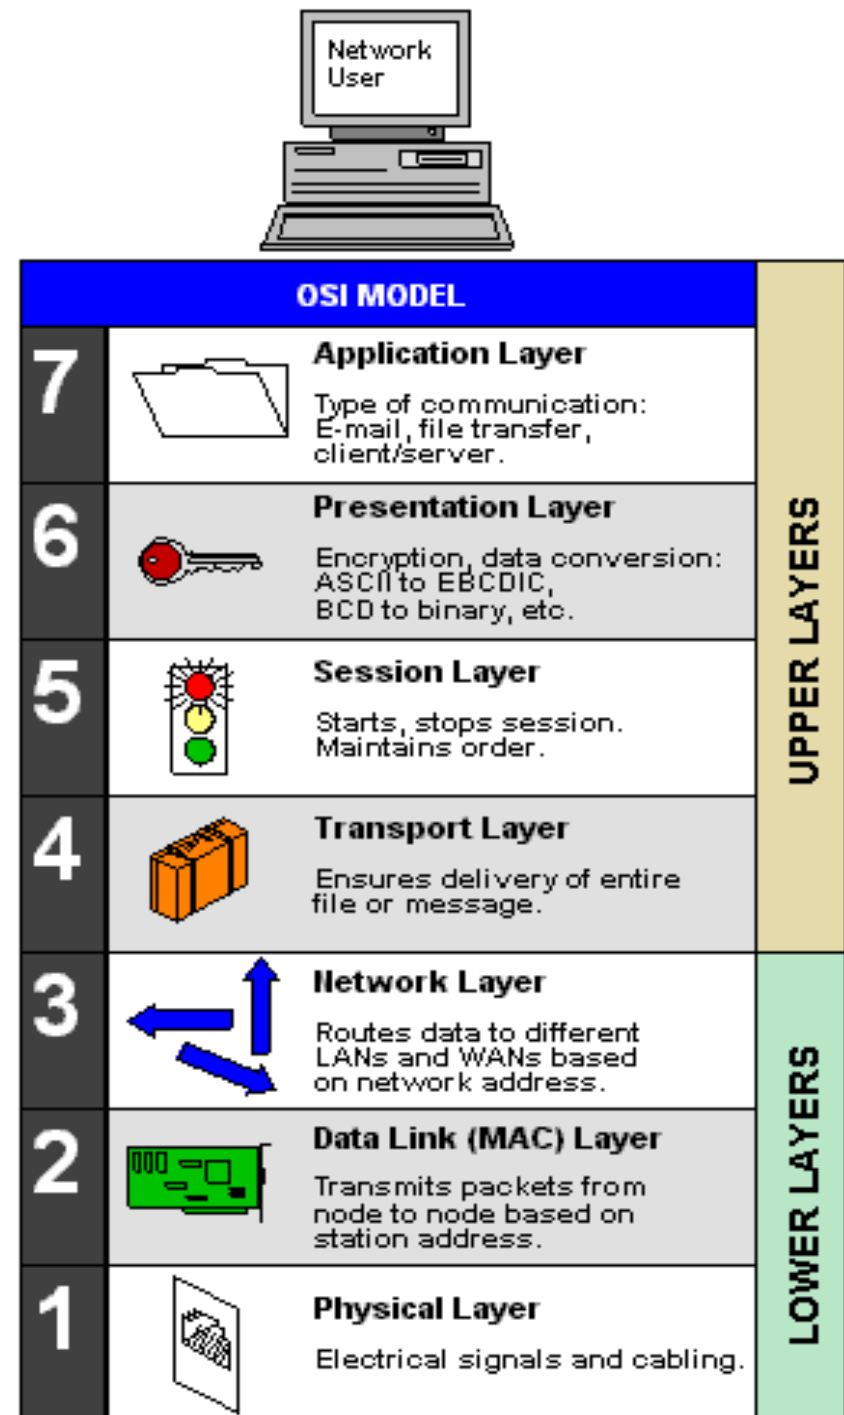

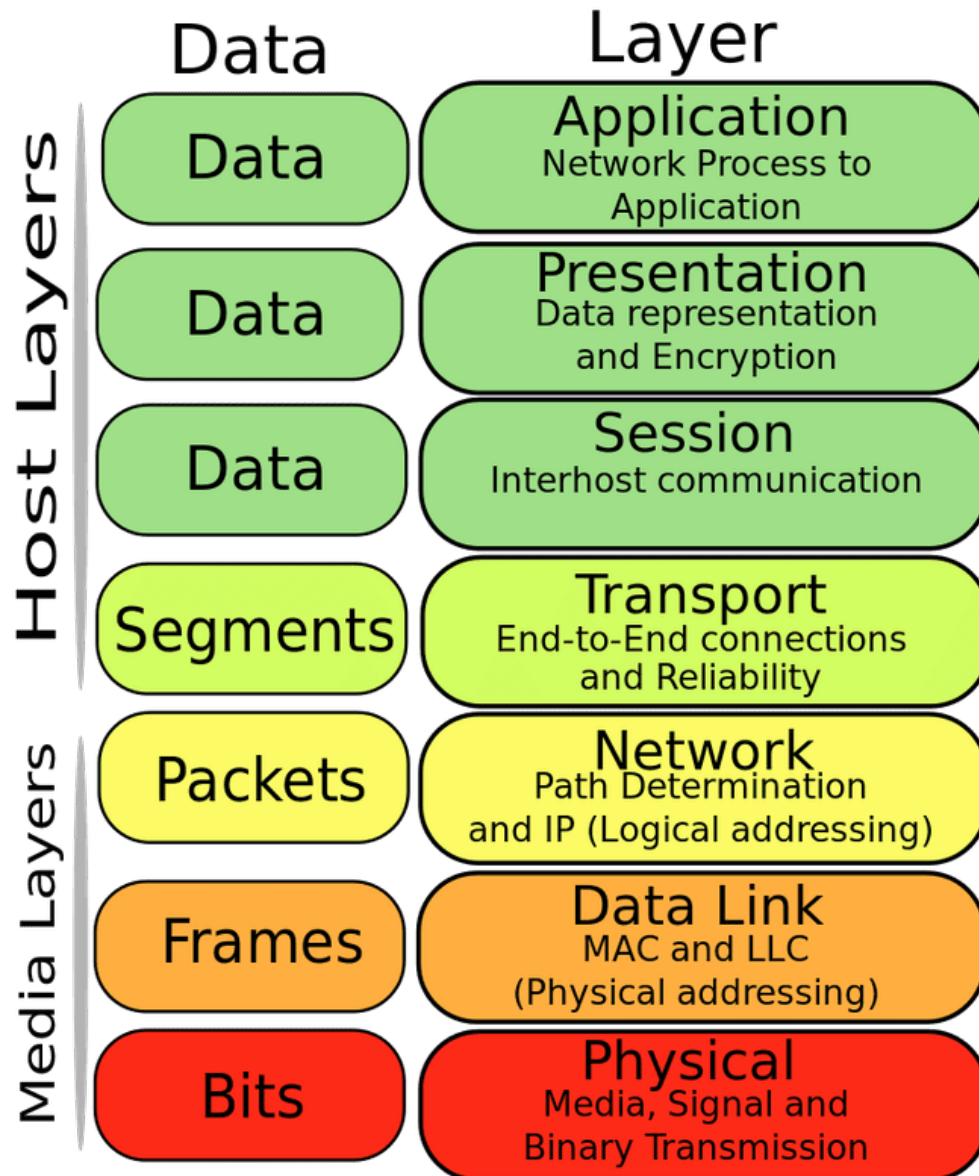

Layer N provides a well defined service to layer N+1 by using the service provided by layer N-1.

Each N Layer only “talks” to Layer N-1 and Layer N+1

Network models

OSI Model

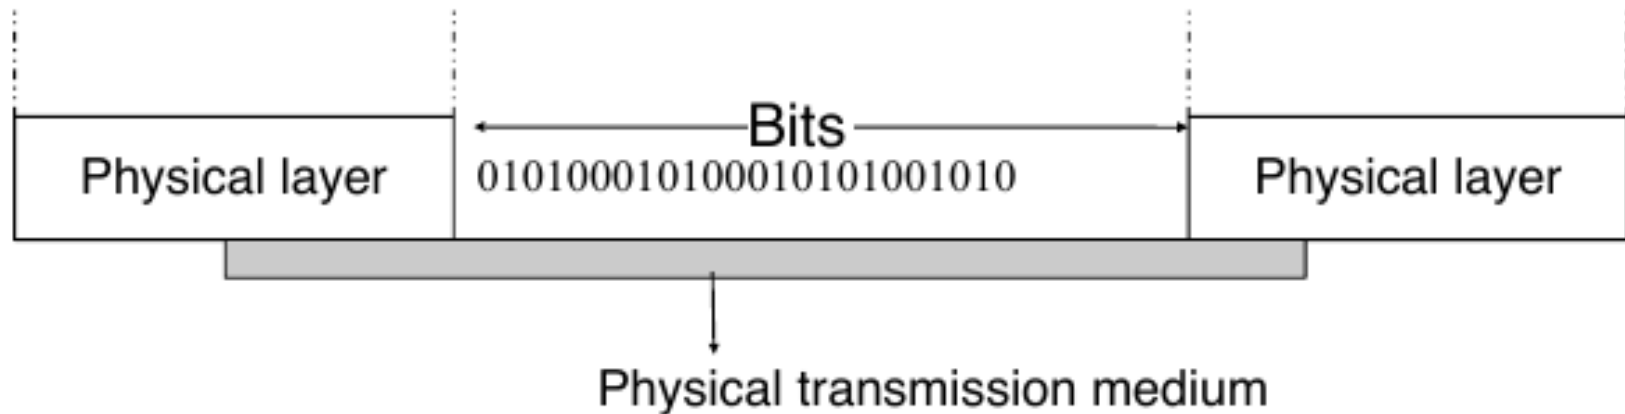

OSI and TCP/IP Model

OSI MODEL

TCP/IP MODEL

Application Layer	Application Layer
Presentation Layer	
Session Layer	
Transport Layer	Transport Layer
Network Layer	Internet Layer
Data Link Layer	Network Access Layer
Physical Layer	

Physical Layer

Goal

Transmit bits between two physically connected devices

Service provided by physical layer

bit transmission and reception

unreliable service

The receiver may decode a 1 while the sender sent 0

Some transmitted bits may be lost

The receiver may decode more bits than the bits that were sent by the sender

Datalink Layer

Goals

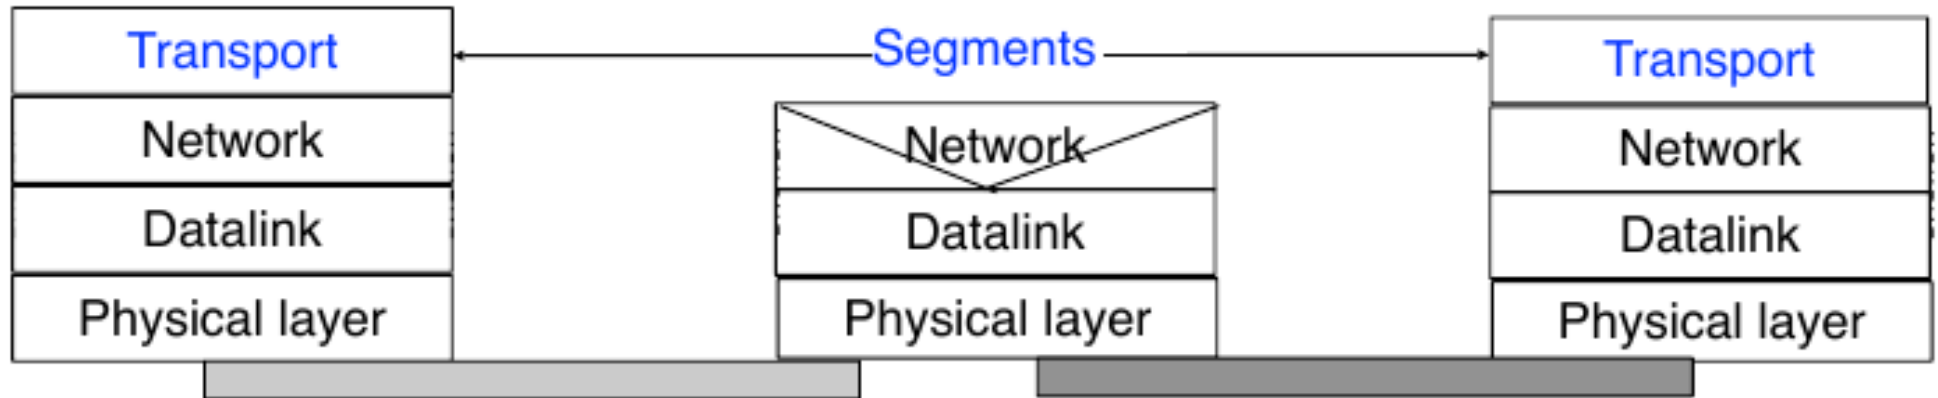

Provide a service that allows the exchange of frames

Frame: structured group of bits
Support local area networks

Services

- Reliable connection-oriented service
- Unreliable connectionless service

Transport Layer

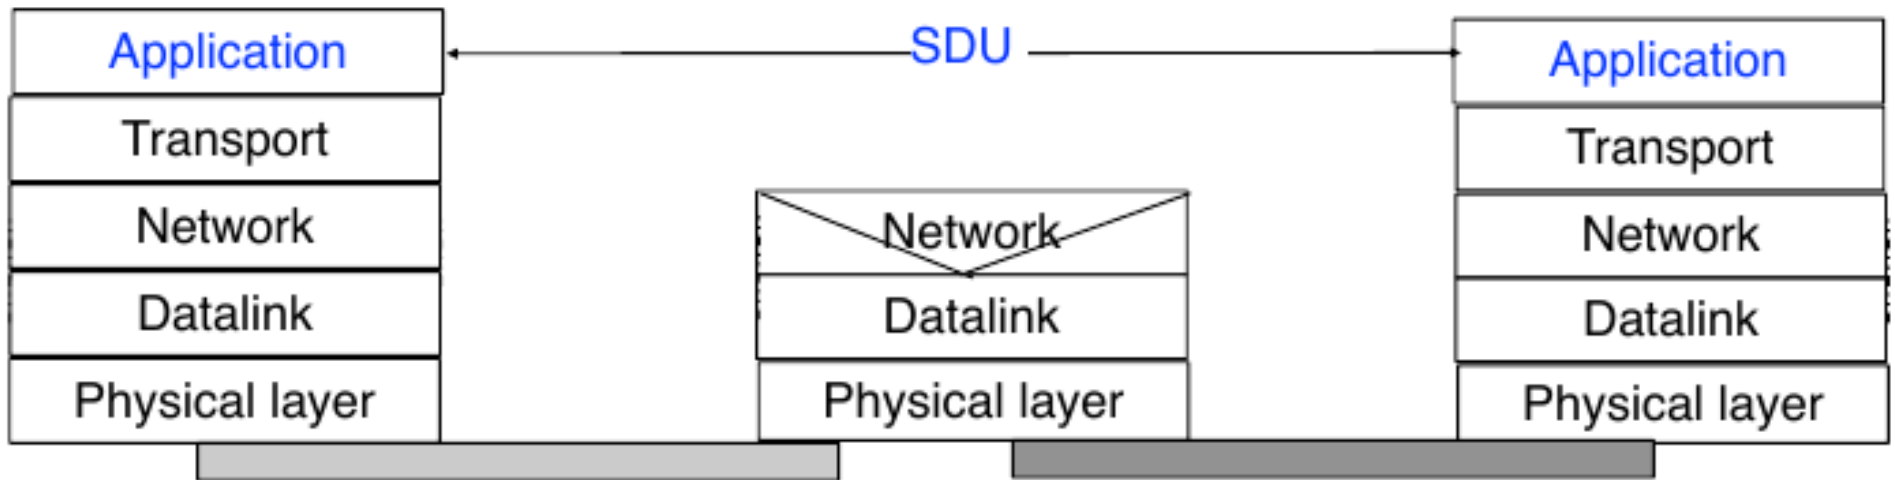

Goals

Ensure a reliable exchange of data between endsystems even if the network layer does not provide a reliable service

Services

Unreliable connectionless service
Reliable connection-oriented service

Application Layer

Goals

Exchange useful information between applications by relying on the transport layer that hides the complexity of the network

Unit of information

Service Data Unit, SDU

Remarks

- People tend to use “packet” as unit of information, if the information transits online (even if the correct term might be “frame” or “segment”)
